

HAIL DAMAGE TO ROOFING: ASSESSMENT AND CLASSIFICATION WILLIAM C. CULLEN

National Roofing Contractors Association Washington, D.C.

erated a renewed interest in hail as a destructive force to roofing. There is an inventory of hail damage information resulting from field investigations and many insurance claims. However, information about the assessment and classification of damage to roofs by falling hailstones is lacking. Part I of this paper suggests procedures for on-the-roof assessment of hail damage. It assigns damage susceptibility factors for eight generic roof systems with respect to damage types. Part II proposes a classification system for rating the resistance of roofing products to hailstones. Hail testing has been carried out in laboratories using simulated hailstones to

Storm damage complaints and large insurance payouts in the Southwestern and Midwestern United States have gen-

impact roofing products for many years. The results have been reported in the technical literature. Using these results, kinetic energy is proposed as the criterion for quantifying hail resistance of roofing products. This allows for making reasonable comparisons between the results of the many different test methods used to measure the hail resistance. Such a system can be useful to standard developers, insurance companies, contractors, manufacturers, owners, Assessment, classification, criteria, damage, hail, kinetic ener-

regulators, researchers and other interested parties. **KEYWORDS** gy, resistance, roofing, test methods.

INTRODUCTION

Hailstorms cause considerable damage to residential and commercial roofing each year. Smith reported that, since 1989, the insurance industry estimates that hail damage to

in the Southwestern and Midwestern United States has gen-

buildings averages \$1.94 billion per year. Hailstorm damage

Average Annual No. of Days

with Hall

erated a renewed interest in hall as a destructive force to roofing. This is reflected in escalating insurance settlements, increasing owner complaints, and requests for information about evaluating and repairing hail damage. Although information on hail tests is reported in technical literature, little deals with the assessment or classification of hail damage to roofing. This paper addresses these subjects. Part I offers guidelines for the assessment of hail damage to commercial and residential roof systems. It asserts that testing may be required to supplement visual observations to identify concealed damage that can adversely affect the waterproofing integrity and the service life of the roofing membrane Part II proposes a classification system for rating the hail

resistance of roof systems. Kinetic energy is used as a quantitative measure to classify the hail resistance of roofs as proposed by Mathey. The threshold criteria used are interpret-

HAIL AND HAILSTORMS It is beyond the scope of this paper to review the theories of hail formation, storm types, storm development, and other

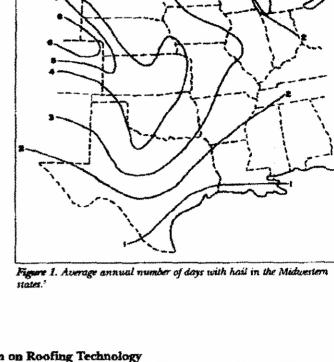

ed from data reported in the technical literature. Several benefits from the establishment of a reasonable classification

theoretical and practical information regarding hailstones and their characteristics. This information can be found in

system are described.

the literature. Hailstorms rarely produce hailstones of uniform size, shape or density. In most cases, these storms produce hailstones that are relatively small and render little danger to roofing materials. However, each year there are rare storms that yield hailstones in the range of 13 to 75 or even 100 mm (% to 3 or even 4 in) in diameter. U.S. Weather Bureau data' show that the most likely areas of the United States to encounter hailstorms lie between the Appalachian and Rocky mountains. A method for predicting the frequency and probability of hail size in the Midwestern states was reported by Friedman.* Figure 1 illustrates the

annual frequency of the number of days on which hail falls that he estimated for the Midwestern states. Using several

Foreword Most roof systems are susceptible to damage resulting from the

rials and design as well as the force produced by the impact of falling hailstones. Other factors, such as age and surface temperature at time of impact, may also come into play. Hail damage can be cosmetic or substantial. The effects of hail damage often can be readily seen. But, visual observation of roof surfaces often does not reveal serious damage. This may include weakening of granular adhesion, fractures, punctures and the like. Damage to the substrate also can

occur. In such cases, testing is required to help determine the

extent of the damage to the roof system's components.

impact of large hallstones falling at high velocities. The extent

of damage depends on the nature of the roof system, i.e., mate-

Unfortunately, some damage may not be apparent until after months or years of exposure. If substantial damage has occurred, the roof system's waterproofing integrity is at risk and its service life threatened. Inspection and Testing A thorough inspection for damage is recommended after exposure to large hailstones. Initially, a "walk over" of the roof is made noting the extent, type and intensity of visible damage. Particular attention should be given to the more vulnerable roof areas including flashings, seams, material edges and unsupported areas. Probe questionable areas to decide if further study is warranted. If substantial damage is suspected, testing may be required. Samples should be taken from the damaged areas. The

samples and the exposed substrates are examined for defects caused by the hailstones impact. The components or plies of

bituminous-based materials can be separated by solvent

extraction or other suitable means to establish the full extent

of concealed damage. This can be accomplished on-site with proper equipment, but it is more conveniently done in a lab-

oratory. Specific testing techniques are required to detect hidden damage to other materials such as single-ply membranes, shingles, metal and inorganic materials. Dumage Grouping Various generic roof systems are susceptible to distinctive types of hail damage. It is beneficial to become familiar with the types of damage associated with generic systems for inspection and testing purposes. Some examples follow:

Unfo. unately, there are a lack of procedures for assessing

hail damage both on actual roofs and on hail-damaged sam-

ples in the laboratory. These procedures need to be developed. Lacking them, the assessment of hail damage sustained

by common roof systems requires system specific analysis.

PART II—HAIL RESISTANCE

joules (1 to 46 ft. lbf).

CLASSIFICATION SYSTEM Test Methods lest methods for impacting roofing targets with simulated hailstones are described in the literature. Some methods use compressed air guns to propel projectiles at targets. Timing devices are used to measure projectile velocity either initially or just prior to impact. Other methods use projectiles dropped on targets from predetermined heights. In each case, the impact energy resulting from the projectile impact can be calculated.

The composition of the commonly used projectiles to simulate hailstones include ice, metal and plastic missiles. They vary considerably in density, shape and size. Consequently, there is considerable debate among researchers regarding the dissipation of energy of the various types of missiles when they impact a target. This is a fruitful subject for further research. A test method, developed at the National Bureau of Standards* (NBS),* uses ice spheres varying in diameter from 25

es in increments of % inch). The spheres are propelled at

velocities of 23 to 40 m/s (75 to 131 ft/s) to impact the target resulting in impact energies varying from about 1.4 to 63

Table 3 relates hailstone size and terminal velocity to

kinetic energy as reported by the National Building Research

Institute of South Africa.º The table gives the data and Figure

2 illustrates these data in terms of the relation between size,

velocity and impact energies achieved by falling hailstones. The data show that the impact energies increase exponentially with the increase in size and velocity of ice spheres. The energy nearly triples from the impact of a 38 mm to a 50 mm (1% to a 2 inches) hailstone from 11 to 30 joules (J) (8 to 22 In 1991, Roontz' reported on hall impact tests on residential roofing products. Ice spheres, 19 to 63 mm (X to 2½ inches) in diameter, were projected at roofing targets at velocities of 20 to

36 m/s (65 to 118 ft/s). The resulting impact energies varied

impact targets with ice projectiles of various shapes, sizes and

densities. The projectiles, up to 75 mm (8 inches) in diameter, were propelled at speeds in excess of 40 m/s (131 ft/s)

resulting in impact energies exceeding 163 joules (120 ft.

At another laboratory,* a pneumatic gun was used to

from about 1.4 to 72 joules (1 to 53 ft. lbf)

lbf). Tests were conducted on a variety of roofing products. *Now the National Institute of Standards and Technology (NIST). †Terminal velocity is the limiting uniform velocity attained by a falling body when the resistance of the air has become equal to the force of gravity. The FMRC method¹¹ determines the potential for hail

damage of roof covers adhered to insulation and various con-

test methods.

The NBS research involved the testing of a variety of asphalt shingle products. Type 235 organic reinforced asphalt shin-

gles were impacted with hailstones at three areas of the shin-

gie tab: at the edge, at areas of no support and at areas of

triple coverage. Testing was performed on shingles applied to

plywood and tongue and groove wood decks with and without organic felt underlayments. The criterion used to define

the endpoint was the impact energy required to fracture the shingle reinforcement. Table 5 summarizes the results of hail

The second measures hall resistance of roof coverings to moderate hail damage (Class I T&G (25x150mm) 30 19 11 MH) by delivering an impact energy of 10.8 joules (8 ft. lbf). Table 5. Test results on Type 235 asphalt, organic shingles: The UL method 12 provides impact resistance data for the evaluation of several different roofing materials and roof coverings. The performance is predicated on the materials and coverings resistance to falling steel balls dropped from predetermined heights thus generating energies consistent with hailstones falling at terminal velocities. Various techniques are used to assess the resulting damage. Table 4 provides the test parameters and the energies produced by the impacting missiles in the ASTM, UL and FMRC age, are reported in Table 7. Test Results

were applied to plywood decks and tested at room temperatures. Table 6 reports minimum energy sufficient to cause indentation, fracture and puncture. Built-up roofing Four types of built-up roof constructions used in the 1960s

Table 7. Minimum hailstone impact energy to damage BUR?

Proceedings of the Fourth International Symposium on Roofing Technology A small body falling at a high velocity can impart the same energy as a large body falling at a slower velocity. Consequently, it is important that impact tests on roofing materials be conducted to simulate the energy generated by actual hailstones falling at their terminal velocity. Severe surface fracture, cracking and puncture damage is quite obvious. Damage to waterproofing integrity or reduction of the intended service life of roofing products often is not

readily apparent from visual observation. In such cases, additional testing is required to reveal the extent of the damage.

Part II of the paper proposes a model for classifying roof sys-

tems as to their resistance to hail damage. The model, based

on the concept of using kinetic energy as the criterion for

appraising the hail resistance of roofing materials, is reason-

ably sound. Several benefits are apparent from utilizing a

classification system. First, using energy as the criterion allows

reasonable comparisons to be made between the results of

current and future methods used to measure the hail resis-

Next, insuring agencies may wish to adopt comparable sys-

tems for defining hail resistance requirements for roof prod-

ucts in hail-prone areas commensurate with hailstone size

and frequency experienced. Standard and code bodies could

For the most part, hail tests, like many other test methods,
